5.1	Usage . . . . .	11
5.2	Reference Library . . . . .	13
	<b>Python Module Index</b>	<b>23</b>

Work with HTTP Request/Response objects, sessions, and more.

---

**Build Status**

---

---

## Installation

---

```
pip install watson-http
```

---

### Testing

---

Watson can be tested with `pytest`. Simply activate your virtualenv and run `python setup.py test`.

---

## Contributing

---

If you would like to contribute to Watson, please feel free to issue a pull request via Github with the associated tests for your code. Your name will be added to the AUTHORS file under contributors.

---

## Table of Contents

---

### 5.1 Usage

---

**Tip:** watson-http also works particularly well with watson-form

---

#### 5.1.1 Creating a Request

Requests can be instantiated directly from the class, or be created based on environ variables.

---

**Note:** Instantiating from the class itself will not populate the Request object with the relevant data from the current server request.

---

##### From the environ

```
from watson.http import messages

def application(environ, start_response):
    request = messages.create_request_from_environ(environ)
    print(request.method)
```

---

**Tip:** watson-http also enables you to deal with other HTTP verbs that may not be accessible by a regular browser. Simply posting HTTP\_REQUEST\_METHOD and setting it to a valid HTTP verb will convert that request to the specific verb.

---

##### From watson.http.messages.Request

```
from watson.http import messages

def application(environ, start_response):
    request = messages.Request('get', get={'get_var': 'somevalue'})
    print(request.method) # get
    print(request.get('get_var')) # somevalue
```

### Dealing with Sessions

**Tip:** You can access many things from the Request, and most work similar to a regular `dict`. These include: headers, server, cookies, get, post, files, url and sessions.

Earlier, we created a request with the `create_request_from_envIRON` method. By default, all requests will be created with the `watson.http.sessions.File` backend for managing sessions. This however can be changed to a different backend by adding the `session_class` argument to the `create_request_from_envIRON` call. `session_class` must inherit from `watson.http.sessions.abc.StorageMixin`. If the class requires any additional configuration (the `http.sessions.file.Storage` class allows you to set the directory sessions are stored in), then you can also pass a dict of options via `session_options`.

```
from watson.http import messages

def application(envIRON, start_response):
    request = messages.create_request_from_envIRON(envIRON, session_class=YOUR_SESSION_CLASS, session_options=YOUR_SESSION_OPTIONS)
```

### 5.1.2 Creating a Response

While you can simply return a list from a WSGI application, you still need to also call the `start_response` method. While this maybe sufficient for smaller applications, anything larger requires a more robust approach. A standard WSGI callable may look like below:

```
def application(envIRON, start_response):
    start_response('200 OK', [('Content-Type', 'text/html')])
    return [b'Hello World']
```

With `watson-http` this code turns into...

```
from watson.http import messages

def application(envIRON, start_response):
    response = messages.Response(200, body='Hello World!')
    return response(start_response)
```

The response body by default is interpreted as utf-8, however this can be modified by accessing the response headers.

```
response = messages.Response(200)
response.headers.add('Content-Type', 'text/html; charset=ENCODING')
```

### 5.1.3 Putting it all together

An example app that outputs get variables may look like:

```
from watson.http import messages

def application(envIRON, start_response):
    request = messages.create_request_from_envIRON(envIRON)

    response = messages.Response(200, body='Hello {name}!'.format(request.get('name', 'World')))
    return response(start_response)
```

When you navigate to `/` you will be presented with 'Hello World!', however if you navigate to `/?name=Simon`, you will be presented with 'Hello Simon!'

## 5.2 Reference Library

### 5.2.1 watson.http

```

1  # -*- coding: utf-8 -*-
2  __version__ = '1.1.3'

94     'json': ('application/json',),
95     'xml': ('text/xml', 'application/xml')
96 }
```

## 5.2.2 watson.http.cookies

**class** watson.http.cookies.**CookieDict** (*input=None*)

A dictionary containing cookies.

A basic extension of the SimpleCookie class from the standard library, but designed to work better with wsgi.

Example:

```
cd = CookieDict()
cookie = cd.add('my_cookie', 'some value')
print(cookie) # my_cookie=some value
print(cd['my_cookie']) # my_cookie=some value
```

**add** (*name*, *value*='', *expires*=0, *path*='/', *domain*=None, *secure*=False, *httponly*=False, *comment*=None)  
Convenience method to add cookies to the dict.

**Parameters**

- **name** – the name of the cookie
- **value** – the value of the cookie
- **expires** – the expiration date for the cookie in seconds
- **path** – the path in which the cookie is valid
- **domain** – the domain in which the cookie is valid
- **secure** – only send cookies over https
- **httponly** – only send over http requests, not accessible via JavaScript
- **comment** – the associated comment with the cookie

**Returns** The morsel that was added to the CookieDict

**delete** (*name*)  
Expire a cookie the next time it is sent to the browser.

**Parameters** **name** – the name of the cookie

**expire** ()  
Expire all the cookies in the dictionary.

**merge** (*cookie\_dict*)  
Merges an existing cookie dict into another cookie dict.

**watson.http.cookies.cookies\_from\_environ** (*environ*)  
Converts a HTTP\_COOKIE from an environ dict into a CookieDict.

### 5.2.3 watson.http.headers

**class** **watson.http.headers.HeaderCollection** (*environ*=None)  
Retrieves header related variables from an environ.

Allows the use of non-capitalized names.

Example:

```
headers = HeaderCollection.from_environ(environ)
print(headers.get('Content-Type'))
```

**\_\_init\_\_** (*environ*=None)

**add** (*field*, *value*, *replace*=False, *\*\*options*)  
Add a header to the collection.

**Parameters**

- **field** (*string*) – The field name
- **value** (*mixed*) – The value of the field
- **replace** (*boolean*) – Whether or not to replace an existing field
- **options** (*kwargs*) – Any additional options for the header

Example:

```
headers = ...
headers.add('Content-Type', 'text/html', charset='utf-8')
```

**classmethod from\_environ** (*environ*)

Instantiate the collection from an existing environ.

**get** (*field*, *option=None*, *default=None*)

Retrieve an individual header or it's option.

Example:

```
# Content-Type: text/html; charset=utf-8
headers = HeaderCollection()
headers.add('Content-Type', 'text/html', charset='utf-8')
option = headers.get('Content-Type', 'charset') # utf-8
```

**Parameters**

- **field** – the header field
- **option** – the option to retrieve from the field
- **default** – the default value if the option does not exist

**Returns** The default value or the value from the option

**get\_option** (*field*, *option=None*, *default=None*)

Retrieve an individual header or it's option.

Example:

```
# Content-Type: text/html; charset=utf-8
headers = HeaderCollection()
headers.add('Content-Type', 'text/html', charset='utf-8')
option = headers.get('Content-Type', 'charset') # utf-8
```

**Parameters**

- **field** – the header field
- **option** – the option to retrieve from the field
- **default** – the default value if the option does not exist

**Returns** The default value or the value from the option

**items** ()

Returns tuple pairs of environ vars and their values.

**set** (*field*, *value*, *\*\*options*)

Add a header to the collection.

Any existing headers with the same name will be removed.

**Parameters**

- **field** (*string*) – The field name
- **value** (*mixed*) – The value of the field
- **options** (*kwargs*) – Any additional options for the header

Example:

```
headers = ...
headers.add('Content-Type', 'text/html', charset='utf-8')
```

**class** `watson.http.headers.ServerCollection` (*environ=None*)

Retrieves server related variables from an environ.

Example:

```
server = ServerCollection(environ)
print(server['SCRIPT_NAME'])
```

**\_\_init\_\_** (*environ=None*)

**items** ()

Returns tuple pairs of environ vars and their values.

`watson.http.headers.convert_to_http_field` (*field*)

Convert a field from Title-Case to HTTP\_UPPER\_CASE.

`watson.http.headers.convert_to_wsgi` (*field*)

Convert a field name from UPPER\_CASE to Title-Case.

`watson.http.headers.fix_http_headers` (*environ, remove=False*)

Add **HTTP\_** to the relevant headers that its not included with.

## 5.2.4 watson.http.messages

**class** `watson.http.messages.MessageMixin`

Base mixin for all Http Message objects.

**class** `watson.http.messages.Request` (*environ*)

Provides a simple and usable interface for dealing with Http Requests. Requests are designed to be immutable and not altered after they are created, as such you should only set get/post/cookie etc attributes via the `__init__`. By default the session storage method is MemoryStorage which will store session in ram.

See:

- <http://www.w3.org/Protocols/rfc2616/rfc2616-sec5.html>
- <http://ken.coar.org/cgi/draft-coar-cgi-v11-03.txt>

Example:

```
request = Request.from_environ(environ)
print(request.method)
print(request.post('my_post_var'))

request = Request.from_dicts(server={'HTTP_METHOD': 'GET'}, get={'get_var': 'somevalue'})
print(request.method) # get
print(request.get('get_var')) # somevalue
```

**\_\_init\_\_** (*environ*)

**classmethod** `from_dicts` (*get, post, server, headers, body*)

@todo Implement.

**host** ()

Determine the real host of a request.

**Returns** X\_FORWARDED\_FOR header variable if set, otherwise a `watson.http.uri.Url` host-name attribute.

**is\_method** (\*methods)

Determine whether or not a request was made via a specific method.

Example:

```
request = ... # request made via GET
request.is_method('get') # True
```

**Parameters** **method** (*string|list|tuple*) – the method or list of methods to check

**Returns** Boolean

**is\_secure** ()

Determine whether or not the request was made via Https.

**Returns** Boolean

**is\_xml\_http\_request** ()

Determine whether or not a request has originated via an XmlHttpRequest, assuming the relevant header has been set by the request.

**Returns** Boolean

**json\_body**

Returns the body encoded as JSON.

**post**

A dict of all POST variables associated with the request.

**Returns** A dict of POST variables

**class** watson.http.messages.**Response** (status\_code=None, headers=None, body=None, version=None)

Provides a simple and usable interface for dealing with Http Responses.

**See:**

- <http://www.w3.org/Protocols/rfc2616/rfc2616-sec6.html>

Example:

```
def app(environ, start_response):
    response = Response(200, body='<h1>Hello World!</h1>')
    response.headers.add('Content-Type', 'text/html', charset='utf-8')
    response.cookies.add('something', 'test')
    start_response(*response.start())
    return [response()]
```

**\_\_init\_\_** (status\_code=None, headers=None, body=None, version=None)

**Parameters**

- **status\_code** (*int*) – The status code for the Response
- **headers** (*watson.http.headers.HeaderCollection*) – Valid response headers.
- **body** (*string*) – The content for the response
- **version** (*string*) – The Http version for the response

**body**

Returns the decoded body based on the response encoding type.

**cookies**

Returns the cookies associated with the Response.

**encoding**

Retrieve the encoding for the response from the headers, defaults to UTF-8.

**raw()**

Return the raw encoded output for the response.

**start()**

Return the status\_line and headers of the response for use in a WSGI application.

**Returns** The status line and headers of the response.

**status\_code**

The status code for the Response.

**status\_line**

The formatted status line including the status code and message.

### 5.2.5 watson.http.sessions.abc

**class** `watson.http.sessions.abc.StorageMixin` (*id=None, timeout=None, autosave=True*)

The base mixin for all session storage adapters.

By default, if no id is specified when the session is created a new session id will be generated. When a user is logged in, it is good practice to regenerate the id of the session id to prevent session hijacking.

If autosave is set to True, then when data is added to the session the save() method will be called. If set to False, the developer will be required to manually call the save() method themselves.

To function correctly sessions require that cookies are enabled in the users browser.

Example:

```
session = SessionStorageMethod()
# where SessionStorageMethod is a valid storage class
session['key'] = 'some value'
session['key'] # 'some value'
```

**\_\_init\_\_** (*id=None, timeout=None, autosave=True*)

**Parameters**

- **id** – the id of the session
- **timeout** – the expiry time from the current time in seconds
- **key** – the key used to reference the session id in a cookie
- **autosave** – save the contents on `__setitem__`

**cookie\_params**

The cookie params used when saving the session id as a cookie.

**data**

The data associated with the session.

**destroy()**

Destroy the session data from storage, but leave the actual session intact.

**exists()**

Determine whether or not the session exists in storage.

**Returns** Boolean whether or not the session id exists.

**generate\_id()**

**Returns** A new session id based on a random 24 char string

**id**

The id of the session.

**load()**

Loads the data from storage into the session. If the session data was set to expire before the current time, destroy the session.

**regenerate\_id()**

Regenerate a new id for the session.

**save()**

Save the contents of the session into storage.

`watson.http.sessions.abc.random()` → x in the interval [0, 1).

### 5.2.6 `watson.http.sessions.file`

**class** `watson.http.sessions.file.Storage` (*id=None, timeout=None, autosave=True, storage=None*)

A file based storage adapter for session data.

By default it will store data in the systems temp directory, however this can be overridden in the `__init__`.

`__init__` (*id=None, timeout=None, autosave=True, storage=None*)

Initialize the File Storage object.

**Parameters** `storage` – where the files should be stored

### 5.2.7 `watson.http.sessions.memcache`

**class** `watson.http.sessions.memcache.Storage` (*id=None, timeout=None, autosave=True, config=None*)

A memcache based storage adapter for session data.

`__init__` (*id=None, timeout=None, autosave=True, config=None*)

### 5.2.8 `watson.http.sessions.memory`

**class** `watson.http.sessions.memory.Storage` (*id=None, timeout=None, autosave=True*)

A ram based storage adapter for session data.

### 5.2.9 `watson.http.uri`

**class** `watson.http.uri.Url` (*url*)

An object based representation of a Url.

`__init__` (*url*)

Initialize the url object.

Create a new Url object from either a well formed url string, a dict of key/values, or a ParseResult.

**Parameters** `url` (*mixed*) – The value to generate the url from.

**subdomain**

Returns the subdomain for the URL. With thanks: <http://stackoverflow.com/questions/1189128/regex-to-extract-subdomain-from-url>

### 5.2.10 watson.http.wsgi

`watson.http.wsgi.get_form_vars` (*environ*, *dict\_type*)

Convert environ vars into GET/POST/FILES objects.

Process all get and post vars from a <form> and return MultiDict of each.
